

## LAB :2 Multi-threaded server for multiple client

### Task:

1. Create a Client script which sends a simple message to the server over a period of time repeatedly (automatic for convenience).
2. Create a server script which creates a new thread for each client and handles that client. For handling, the server sends a message back to the client by their respective thread.

Hint : create a thread for creating new threads for clients. You can put a counter for limiting the number of threads.

Extra (for practice): send 3 arguments from client, 2 numbers and 1 operation. Handle it using a multi threaded server.
